Hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) is an oxygen-derived oxidant involved in multiple redox processes in the cell, ranging from physiological signaling pathways to oxidative damage reactions when it is found at higher concentrations. In the vascular system, H<sub>2</sub>O<sub>2</sub> is metabolized mainly by red blood cells (RBC) due to their very efficient antioxidant systems and high membrane permeability. However, the information regarding H<sub>2</sub>O<sub>2</sub> transport in the human RBC membrane is limited, as neither the exact value of the permeability coefficient (P<sub>m</sub>) nor the permeation mechanisms are known. To explore whether H<sub>2</sub>O<sub>2</sub> permeates through the lipid fraction or protein channels, we studied H<sub>2</sub>O<sub>2</sub> solubility in organic solvents and its permeability in lipid membranes, in order to compare with the RBC membrane. Through measurements of partition constants, we found that H<sub>2</sub>O<sub>2</sub> is 14 and 122000 times less soluble in octanol and hexadecane than in water, anticipating a large thermodynamic barrier to H<sub>2</sub>O<sub>2</sub> permeation by lipid membranes. The P<sub>m</sub> in phospholipid membranes of different compositions, determined using the catalase-latency method, varied from 4×10<sup>-4</sup> to 5×10<sup>-3</sup> cm s<sup>-1</sup>, at 37°C. On the other hand, in human RBC we determined a P<sub>m</sub> of 1.6×10<sup>-3</sup> cm s<sup>-1</sup>. After obtaining these results, we evaluated the potential role of aquaporins as H<sub>2</sub>O<sub>2</sub> transporters by checking the effect of aquaporin inhibitors in H<sub>2</sub>O<sub>2</sub> consumption by RBC, and also by studying H<sub>2</sub>O<sub>2</sub> permeability in RBC devoid of either aquaporin 1 or aquaporin 3. Surprisingly, we could not detect any differences in H<sub>2</sub>O<sub>2</sub> permeability in any case. Altogether, these results provide new information on lipid membrane permeability to H<sub>2</sub>O<sub>2</sub> and a new value for the P<sub>m</sub> in human RBC, which was previously unknown. Additionally, they indicate that H<sub>2</sub>O<sub>2</sub> is not transported by aquaporins in human RBC membranes, suggesting simple diffusion or a still unidentified membrane protein as a more probable pathway.
