## Abstract:

Short running title:

### $[^{99m}\text{Tc}]\text{Tc-HYNIC- EcgDf21}$ for infection foci imaging

Opportunistic infections are a problem of great relevance in public health and the precise detection and localization of infection in the early stages of the disease is of great importance for patient management as well as cost containment. Our proposal seeks to contribute to developing a new agent that meets the needs of diagnosis and follow-up of fungal and bacterial infections, focused on the design of a radiotracer with the potential for recognition of hidden infection foci. Defensins, are plant antimicrobial peptides that, not only show activity against plant pathogens but also against human ones. A short analog of EcgDf1 defensin, EcgDf21d (NH<sub>2</sub>-ERFTGGHCRGFRRCFCTKHC-COOH), was labelled through the formation of a  $^{99m}\text{Tc}$ -HYNIC complex which was assessed for physicochemical and biological behaviour both *in vitro* and *in vivo*.

The  $[^{99m}\text{Tc}]\text{Tc-HYNIC- EcgDf21}$  labelling procedure rendered a single product with remarkably high RCP and stability in the labelling milieu. The Log P value indicated that  $[^{99m}\text{Tc}]\text{Tc-HYNIC- EcgDf21}$  has a hydrophilic behaviour, confirmed by the biodistribution profiles. The optimal uptake value was obtained for *C. albicans* infection model reaching a lesion/muscle ratio of 3, this correlates with *in vitro* binding studies, and the lesion can be definitely observed in the scintigraphic images.

## Introduction

Opportunistic infections are a problem of great relevance not only for patients but also for physicians who must manage the disease. Within the more recurrent nosocomial bacterial species are *Staphylococcus aureus*, *Pseudomonas aeruginosa*, and *Klebsiella pneumoniae*, while invasive fungal infections have been characterized mainly due to the presence of species such as *Candida* spp. and *Aspergillus* spp. Precise and early diagnosis of infectious focus can be difficult and time-consuming due to the diversity and changing spectrum of micro-organisms (m.o) that can cause disease. Therefore, accurate detection and localization of infection and inflammation foci in the early stages of the disease is of great importance for patient management as well as

cost containment (Lucignani, 2007). For such goals, Nuclear Medicine is a valuable tool that uses radioactive compounds (radiopharmaceuticals) for diagnostic purposes consisting of systemically administering a radioactive gamma emitter tracer, whose radiation of high penetrating power can be detected externally (Jain, 2017; Ordonez, 2019; Signore, 2020). This allows for evaluating the functionality of the organs and the biochemistry of the lesions in a non-invasive way to detect alterations associated with various diseases. Many radiopharmaceuticals have been developed as diagnostic agents for Nuclear Medicine such as antibiotics, cytokines, leukocytes and antimicrobial peptides. During the last years, compounds derived from human antimicrobial peptides such as ubiciquidin (Welling, 2004; Meléndez-Alafort, 2009), lactoferrin (Brouwer, 2011), and human neutrophil  $\alpha$ ,  $\beta$ -defensins, among others, have been assessed as potential radiotracers for detection of infections. Particularly, the successful development of  $^{99m}\text{Tc}$ -UBI (29-41) and  $^{68}\text{Ga}$ -UBI(29-41) (Vilche, 2016) as radiopharmaceuticals, stimulated the exploration of new antimicrobial peptides (AMPs) derived from different sources. In this sense, our group focused its interest on defensins, which constitute the largest family of AMPs, components of plant innate immunity and are considered non-toxic to plant and mammalian cells (Zaslhoff, 2002; Thevissen, 2004). These AMPs have compact tertiary structures stabilized by disulfide bonds between highly conserved cysteines, they are small in size, have positive general charge, amphipathic stereochemistry, and broad biological activity, these characteristics make them resistant to variations in pH and temperature. Its cationic nature under physiological conditions, associated with tendency to adopt amphipathic structures would facilitate their interaction and insertion within the walls negative cell and phospholipid membranes of microorganisms. The characteristics described above and the fact that defensins, like other plant AMPs, not only show activity against plant pathogens but also against human ones, have generated great interest in these compounds for the development of new drugs with antibiotic action and as agents for the diagnosis and prevention of infections (Kovaleva, 2020; dos Santos, 2020, Ishaq, 2019; de Oliveira Carvalho, 2011). In this line, our proposal seeks to contribute to developing new agents that meet the needs of diagnosis and follow-up of fungal and bacterial infections, focused on the design of new radiotracers with the potential for recognition of hidden infection foci (Muammad, 2012). For this purpose, we selected a short analog of defensin from the native plant Ceibo, *Erythrina crista-galli*, EcgDf1 (Rodríguez-Decuadro, 2019), which inhibits the growth of

microorganisms of interest such as *Candida* spp and *Aspergillus* spp (Figure 1).

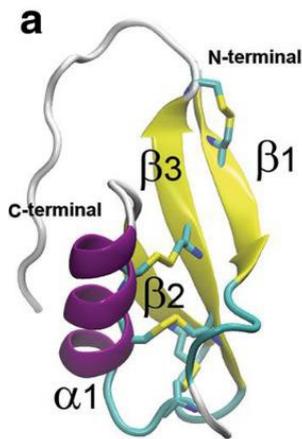

Figure 1: Structure of EcgDf1 defensin (ERFTGGHCRGFRRRCFCTKHC) (Rodríguez-Decuadro, S, 2019)

In order to choose the radionuclide to label the defensin, we selected technetium-99m which continues to occupy a prominent place in diagnostic nuclear medicine mainly due to its wide availability and low cost. As a transition metal, it has rich coordination chemistry which offers many possibilities of oxidation states, cores, and electron donor groups. Labelling biologically active molecules with technetium-99m by the formation of a coordination compound faces an inherent difficulty since it is necessary to develop adequate methods that allow binding the ligand to the metal without altering the biological activity of the molecule of interest (Tehrani, 2021). Our group has been working extensively in the development of radiotracers for infection detection by scintigraphic images based on antibiotics, antifungals, and phages as potential agents using technetium-99m through different radiolabelling approaches (Cardoso, 2016; Fernández, 2017; Reyes, 2014; Terán, 2012). Based on that experience we chose among the multiple strategies available for the radiolabeling of biomolecules one of the most extended methods, the Bifunctional Chelating Agent (BFCA) approach. This involves the conjugation of a peptide or protein with a BFCA and the subsequent formation of a coordination complex with technetium-99m. One of the most popular and effective BFCA is HYNIC (6-hydrazinonicotinamide) (Abrams, 1990). Which is commonly linked to biomolecules through an amide bond formed by the reaction of amine side chains in the biomolecule with an active ester such as N-hydroxysuccinimide (NHS). This makes possible the union of the BFCA to the peptide at a remote location from the biologically active site. In this way, adding a metallic element will not alter the biochemical properties of the peptide. The use of HYNIC requires an additional ligand, such as tricine to complete the technetium coordination sphere, the proposed structure of the complex is shown in Figure 2.

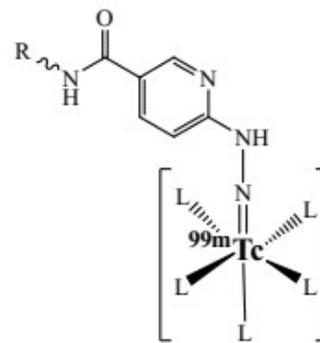

Figure 2 : Proposed complex structure R= defensin EcgDf1, L =tricine ligand

Taking all the above into consideration, we present herein the preparation and evaluation of the  $^{99m}\text{Tc}$ -labeled defensin short analog EcgDf21d with potential application in infection foci imaging. Labelling was performed through the preparation of HYNIC-tricine technetium complex. The biologically active amino acid sequence of EcgDf1 defensin ( $\text{NH}_2$ -ERFTGGHCRGFRRRCFCTKHC-COOH) has its active core in the acid terminal end, so, the peptide was derivatized in the amino terminal group (E) with HYNIC and the coordination sphere of the complex was completed with tricine. The final  $^{99m}\text{Tc}$ -complex was assessed for physicochemical and biological behaviour both *in vitro* and *in vivo* against *Candida albicans*, *Aspergillus niger*, and *Staphylococcus aureus*.

## Results and Discussion

### Radiolabelling

The short synthetic analog of defensin EcgDf21 (ERFTGGHCRGFRRRCFCTKHC) containing 21 amino acids was derivatized on the N terminus with HYNIC as a chelator for technetium-99m, through an amide bond. According to the literature, this amino acid sequence is responsible for the biological activity and the modifications reported enhance selectivity and stability (Rodríguez-Decuadro, 2019)

Different labelling conditions were assessed such as peptide mass (30, 50, 100  $\mu\text{g}$ ), incubation temperature (room temperature 20°C, 70°C, and 95°C), and reaction time (5, 15, and 30 minutes) at pH 4.5. Radiochemical purity (RCP) was determined by HPLC and TLC as described in the experimental section. The results using different radiolabelling conditions are summarized in Table 1.

Table 1: Radiochemical purities (RCP%) of  $[^{99m}\text{Tc}]\text{Tc-HYNIC-EcgDf21}$  achieved using different labelling conditions ( $n=3 \pm \text{SD}$ )

Peptide mass ( $\mu\text{g}$ )		
30	50	100
RCP%		
98.0 $\pm$ 3.1	95.3 $\pm$ 4.8	87.7 $\pm$ 5.5
Incubation temperature ( $^{\circ}\text{C}$ )		
20	70	95
RCP%		
18 $\pm$ 4.3	88.1 $\pm$ 5.0	98 $\pm$ 4.7
Incubation time (min)		
5	15	30
RCP%		
71 $\pm$ 6.8	87 $\pm$ 6.1	98 $\pm$ 3.5

According to these results, the best radiolabelling conditions to obtain the peptide complex, from now on  $[^{99m}\text{Tc}]\text{Tc-HYNIC-EcgDf21}$  were: 30  $\mu\text{g}$  of ligand, pH 4.5, incubation temperature 95 $^{\circ}\text{C}$  during 30 minutes. HPLC analysis shown in Figure 3 revealed the formation of a single product with a retention time ( $rt$ ) of 9,7 min with a RCP higher than 95%. Paper chromatography did not reveal the presence of  $[^{99m}\text{Tc}]\text{TcO}_4^-$ , and the amount of  $[^{99m}\text{Tc}]\text{TcO}_2$  was 6,3  $\pm$  0,31 %  
The  $[^{99m}\text{Tc}]\text{Tc-HYNIC-EcgDf21}$  was obtained with a specific activity of 1,2MBq/ $\mu\text{g}$ .

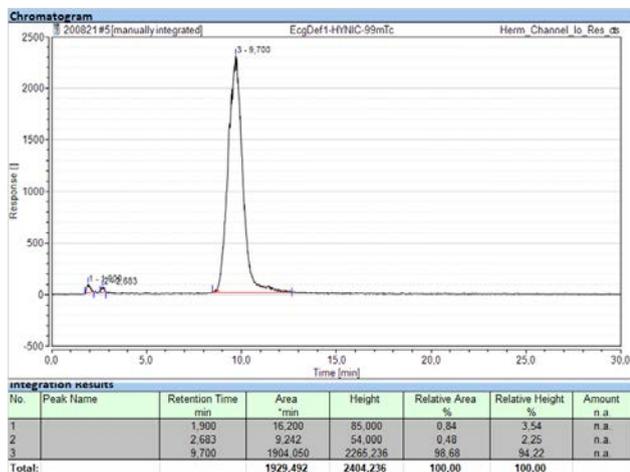

Figure 3: High-performance liquid chromatography profile of  $[^{99m}\text{Tc}]\text{Tc-HYNIC-EcgDf21}$  using 30  $\mu\text{g}$  of ligand, pH 4.5, incubation temperature 95 $^{\circ}\text{C}$  during 30 minutes.

### Physicochemical evaluation

In order to assess the potentiality as radiopharmaceutical of the complex  $[^{99m}\text{Tc}]\text{Tc-HYNIC-EcgDf21}$ , the main physicochemical properties of the radiolabelled peptide were determined namely stability, lipophilicity, and plasma protein binding.

Stability in labelling milieu, in human plasma and after incubation with cysteine as competitive ligand was assessed by HPLC and TLC.

The complex was stable in the labelling milieu for at least 4 hours with RCP higher than 95% and after incubation. Nevertheless, it decomposed after 1 hour of incubation in human plasma indicating a possible enzymatic degradation.

Stability against ligand exchange was studied by incubating with a 5-fold molar excess of cysteine for two hours. This amino acid, usually present in plasma proteins, is an excellent competitive agent to bind technetium.  $[^{99m}\text{Tc}]\text{Tc-HYNIC-EcgDf21}$  presented slight exchange of ligands after 2 hours of incubation, indicating chemical stability under stress conditions.

Lipophilicity was assessed through the determination of the partition coefficient between 1-octanol and phosphate buffer 0.1M pH 7.4.  $[^{99m}\text{Tc}]\text{Tc-HYNIC-EcgDf21}$  was hydrophilic, with a Log P of (-0.60  $\pm$  0.01).

Plasmatic protein binding (PPB) was assessed by size exclusion chromatography at 0.5 and 1 hour. The complex showed moderate PPB, which is a positive property for potential radiopharmaceuticals since only the unbound fraction of  $[^{99m}\text{Tc}]\text{Tc-HYNIC-EcgDf21}$  can bind to microorganism membranes. The physicochemical results are summarized in Table 2.

Table 2: Log P, PPB, and ligand exchange results at 0.5 and 1 hour ( $n=3 \pm \text{SD}$ ).

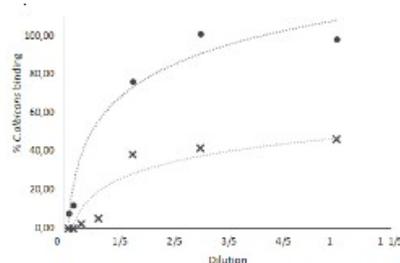

Log P	PPB (%)		Ligand exchange (RCP%)		
	0.5 h	1 h	0.5 h	1 h	2 h
-0.60 $\pm$ 0.01	44.4 $\pm$ 6.3	49.9 $\pm$ 6.7	94.0 $\pm$ 2.2	92.0 $\pm$ 3.5	88.1 $\pm$ 3.1

### Biological evaluation

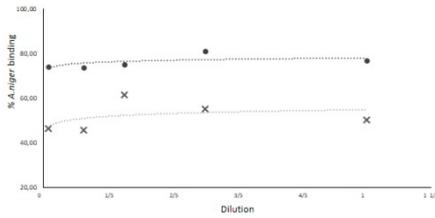

#### In vitro studies

The bacterial and fungi binding assay showed a clear increase in activity retained in the pellet at higher concentrations of m.o cells. Consequently, a plateau in the curve indicates saturation of the complex-m.o interaction. For *Candida albicans*, the binding percentage reached a maximum of 98.75  $\pm$  2.03, for *Aspergillus niger* 81.04  $\pm$  5.9 and for *Staphylococcus aureus* 96.34  $\pm$  3.1, as shown in Figure 4.

a)

b)

c)

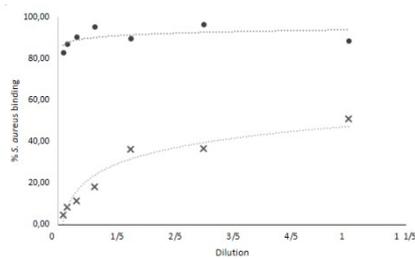

Figure 4: Binding profile of  $[^{99m}\text{Tc}]\text{Tc-HYNIC-EcgDf21}$  with m.o cultures a) *C. albicans*, b) *A. niger* and c) *S. aureus*. The percentage of radio-labelled complex retained versus concentration of m.o is plotted. Full dots: non-blocked; crosses: blocked with non-radiolabelled ligand.

For all three samples of m.o, the  $[^{99m}\text{Tc}]\text{Tc-HYNIC-EcgDf21}$  binding profiles were significantly reduced by competition with the non-radioactive ligand HYNIC-EcgDf21 resulting in a decrease in uptake of approximately 45%, as shown in Figure 4. This indicates the specificity of radiotracer-microorganism binding.

### In vivo studies

Biological evaluation of  $[^{99m}\text{Tc}]\text{Tc-HYNIC-EcgDf21}$  was performed in normal mice (G1) in order to determine the biological distribution of the complex, with special attention on blood pharmacokinetics behaviour, routes of elimination, and accumulation sites. Figure 5 shows biodistribution values of Injected Dose percentage (% ID) of the biological models at 2 hours post administration of the complex.

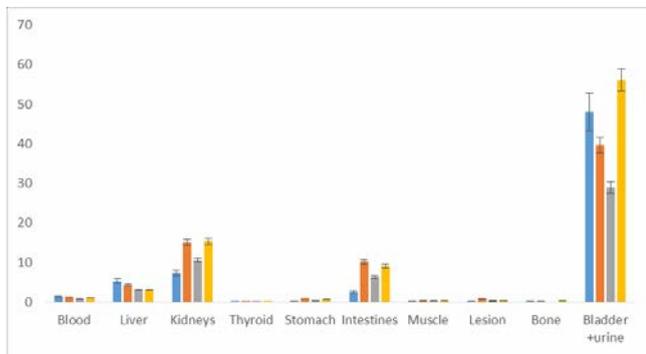

Figure 5: Biodistribution profile of all the biological models at 2 hours post injection of  $[^{99m}\text{Tc}]\text{Tc-HYNIC-EcgDf21}$ . ( $n=3 \pm \text{SD}$ )

The collective accumulation stomach and thyroid of  $[^{99m}\text{Tc}]\text{Tc-HYNIC-EcgDf21}$  was low, indicating that no *in vivo* reoxidation occurs. The highest accumulation organs are kidneys with an average of 15% ID uptake, independently of the biological model. The complex is eliminated mainly by urinary path, 55% ID, in accordance with its Log P value.

The uptake of the complex in the induced lesions (L) and the normal muscle (M) was quantified by measuring samples both during biodistributions (BD) and image quantification for all the groups.

The ratio L/M is shown in table 3, the results between both calculation methods did not show a statistically significant difference (Unpaired T test p value < 0.05 GraphPad Prism version 6 (GraphPad Software, San Diego, CA, USA) except for G3.

Table 3: Lesion (L) to muscle (M) ratio ( $n=3 \pm \text{SD}$ )

L/M ratio	G1 LPS	G2 C.albicans	G3 A.niger	G4 S.aureus
Biodistribution	1.37±0.90	2.7±0.35	0.85 ±0.15	1.31±0.42
Image quantification	1.02±0.02	2.91±0.14	1.7±0.5	1.35±0.6

Despite the high binding values of  $[^{99m}\text{Tc}]\text{Tc-HYNIC-EcgDf21}$  to *in vitro* microorganism cultures, the *in vivo* uptake in animals was only remarkable in G2, *C. albicans*, having almost three times more activity in the lesion than in the normal muscle. Group 3 corresponding to *A. niger* showed slight uptake in scintigraphic images but this behaviour was not confirmed by biodistribution. This difference may be due to the infection foci characteristics that are usually diffuse and difficult to separate from the muscle during dissection, but can be focused in the SPECT image. In the case of G4, both quantification methods led to similar results but there was no significant difference in uptake when compared with G1 LPS sterile inflammation.

Figure 6 shows the scintigraphic images corresponding to animals of G2, G3 and G4.

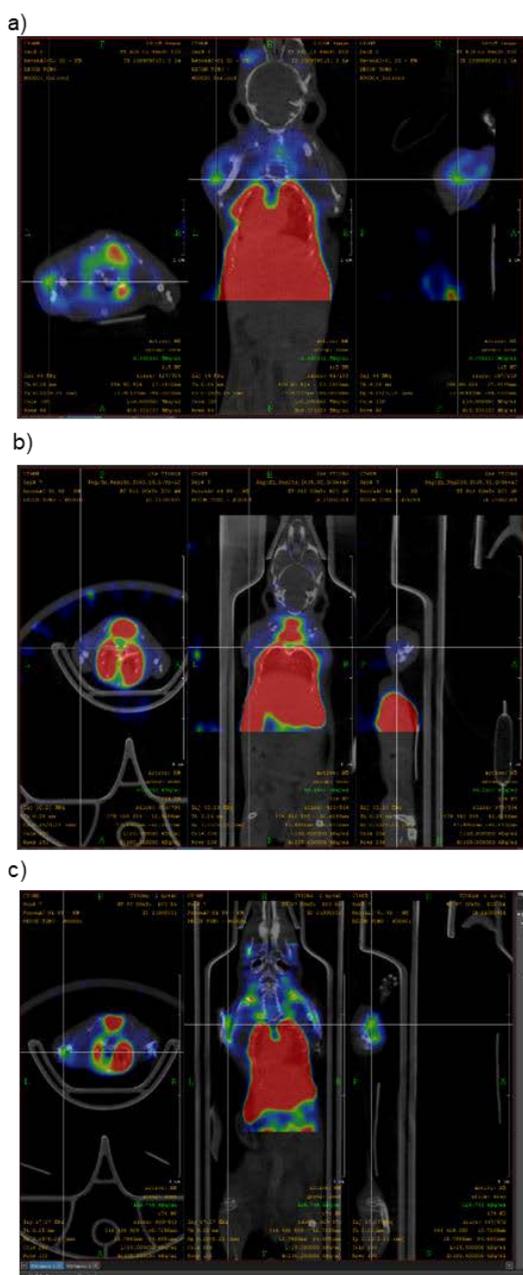

Figure 6: Scintigraphic images of  $[^{99m}\text{Tc}]\text{Tc-HYNIC-EcgDf21}$  in Balb. C mice infected a) *C. albicans*, b) *A. niger* and c) *S. aureus*

## Conclusions

In the present work, we described the development, *in vitro* and *in vivo* evaluation of a new radiolabelled antimicrobial peptide EcgDf21, obtained by preparation of a  $^{99m}\text{Tc}$  HYNIC complex. The labelling approach is very simple because the BFCA moiety can be easily added to the peptide and this ligand can be maintained in freezer for several weeks. Furthermore, the labelling procedure rendered a single product with remarkably high RCP and stability in labelling milieu.

Physicochemical evaluation showed that the  $[^{99m}\text{Tc}]\text{Tc-HYNIC-EcgDf21}$  complex has adequate properties including high stability in milieu and against cysteine maintaining high RCP during the

time of observation that represents the time needed for biological evaluation. The challenge against human plasma suggested that the complex may suffer enzymatic degradation *in vivo*.

*In vitro* studies of binding to m.o cultures, showed that  $[^{99m}\text{Tc}]\text{Tc-HYNIC-EcgDf21}$  maintains its capability of interacting with the pathogens assessed at several dilutions, being all above 70% at least at the 1/5 dilution. This is a good indicator that the peptide remains biologically viable despite de chemical modifications derived from the radiolabelling process. Complementary competition studies confirmed the specific binding of the  $[^{99m}\text{Tc}]\text{Tc-HYNIC-EcgDf21}$  to m.o showing a marked decrease when incubated with the competing non-radiolabelled ligand.

Regarding biological evaluation in animal models, the biodistribution profile for both sham and injured groups revealed that the complex does not suffer *in vivo* reoxidation of  $^{99m}\text{Tc}$  as the %ID in stomach and thyroid are negligible, these results are in accordance with the physicochemical studies that indicate chemical stability in time and against cysteine. The Log P value indicates that  $[^{99m}\text{Tc}]\text{Tc-HYNIC-EcgDf21}$  has a hydrophilic behaviour which is confirmed by the biodistributions, where a mean of 55% of the injected dose is eliminated by urine.

As the objective of this work was to develop and evaluate a potential radiotracer for infection foci, the uptake in induced lesions, both by m.o or sterile inflammation was crucial. One of the characteristics required for this kind of compounds is its ability to discriminate between infection and inflammation, the model of sterile inflammation represented by G1, LPS showed no interaction with  $[^{99m}\text{Tc}]\text{Tc-HYNIC-EcgDf21}$ , this was confirmed both through biological samples ( $L/M = 1.02 \pm 0.02$ ) and image quantification. In the case of G4 (*S. aureus*), the uptake value was similar to G1,  $1.02 \pm 0.2$ , and  $1.3 \pm 0.6$  respectively, despite the good profile obtained *in vitro* with this culture. This behaviour can be explained by the characteristics of the *S. aureus* infection which forms a membrane that encapsulates the foci, preventing the penetration of the complex.

G3 (*A. niger*) presented a low L/M ratio although it is statistically different from the profile shown by G1 and G4 it is not good enough to clearly discriminate the lesion. The optimal value was obtained for the *C. albicans* model reaching an L/M ratio of 3, this correlates with *in vitro* binding studies, and the lesion can be definitely observed in the scintigraphic images.

Lesion uptakes are modest in comparison with other radiolabelled peptides cited in bibliography, for example  $[^{99m}\text{Tc}]\text{Tc-HYNIC-UBI29-41}$  presented accumulation in infected tissues with L/NT ratios of 2–3, and no accumulation in tissues with inflammation (Gandomkar,2009).  $^{99m}\text{Tc}$ -labeled synthetic fragment of human lactoferrin (hLF1–11) showed a T/NT ratio of 3.5 to 4 in animal models of infection (Browner, 2008). Human  $\beta$ -defensin 3 (HBD-3) was labelled and the complex  $^{99m}\text{Tc}$ -labeled HBD-3 was able to discriminate *S. aureus* infection from sterile inflammation with T/NT of 5.7 (Follacchio, 2019).

In this work, the development of a new radiolabelled antimicrobial peptide for infection imaging was achieved.  $[^{99m}\text{Tc}]\text{Tc-HYNIC-EcgDf21}$  showed adequate *in vitro* behaviour and preclinical studies revealed that the peptide structure can differentiate between sterile inflammation and infection in *C.albicans* lesions. Nevertheless, the other infections could not be clearly discriminated *in vivo* despite having very good *in vitro* binding profiles. The general pharmacokinetic behaviour makes this a

basic structure worthy to deepen its study. Slight modifications to the peptide sequence are currently being studied in order to improve the in vivo behaviour and image performance.

## Experimental Section

### Materials

[<sup>99m</sup>Tc]TcNaTcO<sub>4</sub> was obtained from a commercial [<sup>99</sup>Mo]Mo/[<sup>99m</sup>Tc]Tc generator (Tecnonuclear, Argentina). All laboratory chemicals were reagent grade and were used without further purification. HYNIC, L-cysteine, Tricine, SnCl<sub>2</sub>·2H<sub>2</sub>O, bovine serum albumin (BSA) and trifluoroacetic acid (TFA) were purchased from Sigma-Aldrich. Solvents for chromatographic analysis were HPLC grade.

The peptide of sequence EFTGGHCRGFRRCFCTKHC (PM: 2558) was synthesized by NovoPro Bioscience, Inc (China) with purity higher than 90%, analysed by reverse phase HPLC (RP-HPLC) and MS.

Activity measurements were performed either with a dose calibrator (Capintec CRC-5R) or with a scintillation counter (3x3'). NaI (TI) crystal detector attached to an ORTEC monochannel analyser. Paper radiochromatography was carried out on Whatman 1 support and scanned with a radiochromatograph EZ-SCAN Carroll & Associates, SRI – model 302.

HPLC analysis was carried out on Thermo Scientific UltiMate 3000 using a reverse phase column (Waters DeltaPak (150 x 3.9mm C18 5µm, 300Å). Elution was performed at 1.0 mL/min flow rate with a binary gradient system of 0.1% trifluoroacetic acid in water as mobile phase(A) and 0.1% trifluoroacetic acid in acetonitrile as mobile phase (B). The elution profile was as follows: 2-5 min 2% B, 5-10 min 2-50% B, 10-20 min 50% B, 20-25 min 50-70% B. Detection was accomplished with a 1"x1"NaI (TI) crystal scintillation detector (Xiangli Liu et al, 2011)

### Conjugation of EcgDf21with HYNIC

650 µg NHS-HYNIC dissolved in 325 µL DMSO was slowly added to 2 mL solution of peptide and incubated in darkness for 30 minutes. This solution was purified by Sep-Pak C18 Cartridge to remove non-bound HYNIC. EcgDf21-HYNIC solution was stored at -20°C under N<sub>2</sub> atmosphere until use.

### Preparation of [<sup>99m</sup>Tc]Tc-HYNIC- EcgDf21 complex

The labelling process consisted of the preparation of two solutions namely: the conjugated peptide EcgDf21-HYNIC, 1 mg/mL, (A), and the coligand and reducing agent containing 0,3 mg/mL of Tricine and 1.1 mg/mL of SnCl<sub>2</sub> (final pH= 4.5), (B).

An aliquot of 30 µL of solution A was added to 30 µL of B. After homogenization, 100µL of [<sup>99m</sup>Tc]NaTcO<sub>4</sub> (37 MBq/mL, 1mCi/mL) were added and incubated during 30 minutes at 95°C. Radiochemical purity of the complex (RCP) was assessed by reverse phase HPLC. The presence of free [<sup>99m</sup>Tc]TcO<sub>4</sub><sup>-</sup> was determined by chromatography in Whatman1 as stationary phase and NaCl 0.9% as mobile phase (Rf=1) measured in a radiochromatograph scanner Scan-Ram (LabLogic). [<sup>99m</sup>Tc]TcO<sub>2</sub> (colloid) was determined by measuring the retained activity in the HPLC column.

### In vitro evaluation

#### Stability in labelling milieu

[<sup>99m</sup>Tc]Tc-HYNIC-EcgDf21 was incubated in the labelling milieu at room temperature for 0.5, 1, 2, and 4-hours post labelling and the RCP was assessed using the reference system mentioned above.

#### Stability in plasma

*In vitro* stability was assessed by incubating the complex (200 µL) with fresh human plasma (1000 µL) at 37°C. Samples of 150 µL were collected at 0.5 and 1 hour and precipitated with 150 µL of cold absolute ethanol (-15°C) and cooled in a freezer for 5 minutes to induce precipitation. After centrifugation at 156 g for 5 min at 0°C, the pellet was carefully separated from the supernatant and an aliquot of the latter was analysed by HPLC with the reference system.

#### Stability in the presence of competing ligands

A sample of [<sup>99m</sup>Tc]Tc-HYNIC-EcgDf21 (200 µL) was incubated with 1000 µL of a solution of 5 molar excess of L-cysteine at 37°C. RCP was determined after 0.5, 1, 2 and 3 hours by HPLC analysis as described above. (Von Guggenberg, 2004)

#### Lipophilicity

Lipophilicity was determined as the partition coefficient of 1-octanol/phosphate buffer (0.1M, pH 7.4) (Goodman&Gilman, 2007). In a centrifuge tube, 2 mL of 1-octanol and 2 mL of phosphate buffer 0.1 M pH 7.4 were mixed. 100 µL of complex were added and shaken on a vortex mixer for 2 minutes. The mixture was centrifuged for 5 minutes at 1113 g; an aliquot of each phase (n=2) was measured in a solid scintillation counter. Partition coefficient (P) was calculated as the mean activity value of the organic phase divided by the aqueous one; lipophilicity was expressed as log P (Trejtnar, 2002).

#### Protein binding (PPB)

Binding to plasma proteins was determined by size exclusion chromatography. The complex (50 µL) was incubated with fresh human plasma (450 µL) at 37°C up to 1 hour. At 30 and 60 minutes, 25 µL samples were seeded in a size-exclusion chromatography column (Microspin G-50, GE Healthcare, Buckinghamshire, UK). Columns were centrifuged at 1113 g for 1 minute and activity of the eluate and the column was measured in a solid scintillation counter.

The PPB% was calculated as:

$$\left(\frac{\text{net activity eluted}}{\text{total activity}}\right) \times 100$$

being total activity (eluted + retained in the column) (n = 3).

#### In vitro microbiological studies

To evaluate the capacity of the complex to bind to different pathogenic m.o *C. albicans* ATCC 101231 (yeast), *A. niger* CCMG17 (filamentous fungus, Cátedra de Microbiología General Collection CCMG, Facultad de Química, Montevideo, Uruguay) and *S. aureus* ATCC 25923 (Gram positive bacteria) were selected. *C. albicans* and *S. aureus* concentrations were estimated by OD600 and verified by plate count. The initial suspension of *A. niger* was prepared as follows: 25 mL of malt extract medium (12.5%) inoculated with 2 mL of a 109 conidia/mL suspension in fresh malt extract medium previously filtered

(mycelium free), was incubated at 28°C and 150 rpm until germ tube emergence (~5 h). The inoculum was counted in a Neubauer chamber. The culture was centrifuged for 5 min at 3000g at room temperature in glass tubes (Corex). The supernatant was discarded, the pellet was re-suspended in 2 mL of minimal medium (Pontecorvo et al., 1953), and aliquoted at 0.4 mL in Eppendorf for the binding assay. The aliquots were stored at 4°C for 24 h, and thermostatted at 28°C for 5-10min before performing the assay.

Bacteria and yeast binding was performed according to the following technique (Cardoso, 2016). Briefly, 7 serial dilutions from an initial microorganism suspension of 0.4 mL containing 1-3x10<sup>7</sup> CFU/mL in phosphate buffer 14 mM pH 7.4 (buffer A) were done with NaCl 0.9 % (n=3). Each dilution was added with 0.8 mL of buffer E (1vol. 0.1% Tween 80 in buffer A, 1 vol. 0.04% acetic acid). After 15 min at 4°C, an aliquot of 0.1 mL complex (~740 KBq) was added to each tube and incubated for 1 h at 4°C. The entire series was assessed for radioactivity and centrifuged at 13800 g for 5 minutes at 4°C. The supernatant was discarded, the pellet re-suspended with 1 mL of solution E, and centrifuged again at 13800 g for 5 minutes at 4°C. The supernatant was carefully discarded avoiding disturbing the pellet; its final activity was measured. The binding percentage was calculated as:

$$(Net\ Pellet.act/Net\ Total.act) \times 100.$$

Being total activity (*supernatant+pellet*) (n=3)

In order to assess the binding specificity of the complex to the m.o, a competition binding assay was carried out. Each culture was pre-incubation with a solution of 10-fold molar excess of the non-radiolabelled EcgDf21-HYNIC as competitor during 1h, after that the binding assay was performed as previously described.

### **In vivo evaluation**

All biological studies were performed in compliance with the national laws of animal experimentation and approved by the Ethics Committee of the Faculty of Chemistry (N° Protocol 101900-000629-14), Universidad de la República, Uruguay. Biological evaluation was conducted in Balb C female mice, 12-14 weeks old, weighing between 25±2 g (n=3). Five groups of animals were assessed as follows: G0 = sham, G1 = sterile inflammation, G2 = *C. albicans* infection, G3 = *A. niger* infection, and G4 = *S. aureus*. Injury induction involved subcutaneous injection in the left foreleg according to the conditions described below:

- Group 1: Sterile inflammation induced with 100 µL 1x10<sup>9</sup> Lipopolysaccharides (LPS) suspension in NaCl 0.9 % 72 hours before biodistribution studies. (Fernández, 2017)

- Group 2: Fungal infection induced with 100 µL *C. albicans* 1x10<sup>9</sup> CFU fresh culture, 72 hours before biodistribution studies

- Group 3: Fungal infection induced with 100 µL *A. niger* 1x10<sup>9</sup> CFU fresh culture (in conidia phase) 7 days before biodistribution studies

- Group 4: Bacterial infection induced with 100 µL *S. aureus* 1x10<sup>9</sup> CFU fresh culture, 72 hours before biodistribution studies. Mice were maintained in hygienic housing conditions, with cycles of 12/12 light / dark hours and temperature of 22 ± 2°C, with food and water ad libitum.

The biodistributions were performed with [<sup>99m</sup>Tc]Tc-HYNIC-EcgDf21, diluted in saline solution, it was injected into lateral tail vein (0.1 mL with a maximum activity of 1.11 MBq (30µCi), and its biodistribution was studied at 2 hours post injection. Animals were sacrificed by cervical dislocation and the organs of interest were removed, and urine, blood, muscle, and bone samples were also collected. Results were expressed as percentage dose per gram of tissue. Ratio lesion/muscle (L/M) were calculated.

Image acquisition was performed 2 hours post injection, animals were anaesthetized with 2.5% isoflurane flow 1.5-2.0 mL/min on O<sub>2</sub>. Scintigraphies were acquired in a SPECT/CT camera (NanoScan, Mediso). Reconstruction was performed with the OSEM iterative method. Analysis and quantification of images were done with PMOD 3.8 software.

## **Acknowledgments**

The authors thank CSIC for financial project 2014, ANII PEDECIBA-Química, CMNIM-Udelar for Technetium supply, CUDIM Preclinical area for images acquisition, Roberto Castro for support in microbiological studies and Carolina Brindisi for support in radiochemical assays.
